Operational Issues Exporter (Datasette SQL Query)

This script queries the `operational_issue` table from the Digital Land Datasette and exports a CSV summarising the **daily count of issues** over the last 6 months.

Purpose:

To track the number of operational issues logged per day, using Datasette's SQL endpoint and exporting it for reporting or monitoring purposes.

What It Does:

- Constructs a SQL query to:
  - Count issues per `[entry-date]` from the `operational_issue` table
  - Filter to only include rows from the **last 6 months**
  - Group by `[entry-date]`
- Sends the SQL query to the Datasette JSON API
- Parses the result into a DataFrame
- Renames `[entry-date]` to `entry_date` (for consistency)
- Saves the result as `operational_issues.csv` in a specified output directory

In [ ]:
```python
import requests
import pandas as pd
import urllib.parse
import os
import argparse

def sql_queried_datasette_tables(urls: dict, sqls: list, save_dir: str):
    """
    Fetches data from a dictionary of Datasette URLs using optional SQL queries
    and saves each result as a CSV file in the specified directory.

    Args:
        urls (dict): Mapping of table names to Datasette base URLs.
        sqls (list of str): SQL queries corresponding to each URL.
        save_dir (str): Directory path where the resulting CSV files will be saved.

    Raises:
        ValueError: If the lengths of the URLs and SQL lists do not match.
    """
    if len(urls) != len(sqls):
        raise ValueError("The number of URLs and SQL queries must match.")

    # Ensure the output directory exists
    os.makedirs(save_dir, exist_ok=True)

    # Iterate over each (name, URL) and associated SQL
    for (name, url), sql in zip(urls.items(), sqls):
        try:
            # Define the output CSV filename
            csv_name = f"{name}.csv"

            # Encode SQL query and construct JSON API URL
```

```
            encoded_sql = urllib.parse.quote(sql)
            full_url = f"{url}.json?sql={encoded_sql}&_shape=array"

            print(f"Fetching: {name} from SQL URL:\n{full_url}")

            # Fetch JSON data and load into DataFrame
            response = requests.get(full_url)
            response.raise_for_status()
            data = response.json()
            print(f"Rows returned: {len(data)}")
            df = pd.DataFrame(data)

            # rename columns to match expected
